Mean					

The mean, or average, is the sum of all the values in a dataset divided by the number of values. It provides a measure of the central tendency of the data.

$$\mathsf{Mean}(\mu) = \frac{1}{N} \sum_{i=1}^{N} x_i$$

Example:

For the dataset X = [2, 4, 6, 8, 10],

$$\mu = \frac{2+4+6+8+10}{5} = 6$$

Varianc					

Variance measures the spread of the data points around the mean. It indicates how much the data varies from the mean.

Variance
$$(\sigma^2) = rac{1}{N}\sum_{i=1}^N (x_i-\mu)^2$$

Example:

For the dataset X = [2, 4, 6, 8, 10],

$$\sigma^2 = \frac{(2-6)^2 + (4-6)^2 + (6-6)^2 + (8-6)^2 + (10-6)^2}{5} = 8$$

Mean and Variance Visualization

Standard deviation is the square root of the variance. It provides a measure of the spread of the data points in the same units as the data itself.

Standard Deviation(σ) = $\sqrt{Variance}$

Example:

Using the variance calculated previously,

$$\sigma = \sqrt{8} \approx 2.83$$

Covaria	nce				

Covariance measures the degree to which two variables change together. If the covariance is positive, the variables tend to increase together; if negative, one variable tends to increase when the other decreases.

Covariance(Cov(X,Y)) =
$$\frac{1}{N} \sum_{i=1}^{N} (x_i - \mu_X)(y_i - \mu_Y)$$

Example:

For the datasets X = [2, 4, 6] and Y = [3, 6, 9],

$$\operatorname{Cov}(X,Y) = \frac{(2-4)(3-6) + (4-4)(6-6) + (6-4)(9-6)}{3} = 6$$

Types of Supervised Learning Problems

Regression

- Used when the output label is a continuous variable
- For example, linear regression, predicts a continuous target variable as a linear combination of input features.

Types of Supervised Learning Problems

Classification

- Used when the output label is categorical.
- For example, linear classification, splits the data into different categories

- Consider a function y = 2x + 1
- Here we introduce a new notation y = f(x) = 2x + 1
- What this means is that we have a function f(x) which has x as its variable.
- If we have different x values we will have different values of f(x)

Review	Python	Statistics	Supervised Learning	Linear Regression	Multivariable Linear Regression
oo	ooo	00000000000	000	000000000000000000000000000000000000	

- For f(x) = 2x + 1 and setting x = 1 we have f(x) = 3
- For f(x) = 2x + 1 and setting x = 0 we have f(x) = 1
- For f(x) = 2x + 1 and setting x = -1.5 we have f(x) = -2

- We believe that datasets are a representation of underlying models.
- Models which can be represented as functions of features i.e. input to output mappings.
- For example, we can build a model to forecast weather, we can use the features humidity, current temperature and wind speed to estimate what the temperature will be tomorrow.
- Here we have f(x) representing the tomorrow's temperature and x being a vector containing humidity, current temperature and wind speed.

Review	Python	Statistics	Supervised Learning	Linear Regression	Multivariable Linear Regression
oo	ooo	00000000000	000	00000000000000000	

- Our task here is to figure out what f(x) is, using the data available to us.
- Here f(x) is called a model.
- ▶ In other words, we want to find a model that fits the data.

It would be easier to have a "framework" of the model ready and find the model parameters using the data.

$$- f(x) = w_1 x + w_0 - f(x) = w_2 x^2 + w_1 x + w_0 - f(x) = \frac{1}{e^{-(w_1 x + w_0)} + 1}$$

- The numbers w_0 , w_1 and w_2 are called model parameters.
- We often write the model as f(x; w), stacking all parameters to a vector w.

Structure of a dataset

- In a dataset we have many data.
- We can represent each piece of data as (x_i, y_i) , i = 1, 2, 3, ...
- \blacktriangleright x_i is called the feature and y_i is called the label.
- ▶ The relationship between x_i and y_i and the model f is $f(x_i) = y_i$

Review	Python	Statistics	Supervised Learning	Linear Regression	Multivariable Linear Regression

How would you fit a line?

Can you find a line that passes through (0,0) and (1,1)?

- The "framework" of the model is $f(x) = w_1 x + w_0$
- ▶ The data is (x = 0, f(x) = y = 0) and (x = 1, f(x) = y = 1).
- The process of finding a model to fit the data is to find the values of w₁ and w₀.

Is Your Model a Good Fit?

- How would you determine if your model is a good fit or not?
 - How will you determine this?
 - Is there a quantitative way?
- We now introduce a new notation $f(x_i) = \hat{y}_i$ here the $\hat{\cdot}$ represents $f(x_i)$ is a prediction of y_i .

- An error function quantifies the discrepancy between your model and the data.
 - They are non-negative, and go to zero as the model gets better.
- Common Error Functions:
 - Mean Squared Error:

$$\mathsf{MSE} = \frac{1}{N} \sum_{i=1}^{N} ||y_i - \hat{y}_i||^2$$

- Mean Absolute Error:

$$\mathsf{MAE} = \frac{1}{N}\sum_{i=1}^{N}|y_i - \hat{y_i}|$$

In later units, we will refer to these as cost functions or loss functions.

Least Square Solution

Model:

$$f(x) = w_1 x + w_0$$

Loss:

$$J(w_0, w_1) = \frac{1}{N} \sum_{i=1}^{N} ||y_i - f(x_i)||^2$$

▶ Optimization: Find w_0 , w_1 such that $J(w_0, w_1)$ is the least possible value (hence the name "least square").

Least Square Solution: Using Pseudo-Inverse

For N data points (x_i, y_i) we have,

$$\hat{y_1} = w_0 + w_1 x_1$$

 $\hat{y_2} = w_0 + w_1 x_2$
 \vdots
 $\hat{y_N} = w_0 + w_1 x_N$

Review Python Statistics Supervised Learning Linear Regression Multivariable Linear Regression

Least Square Solution: Using Pseudo-Inverse

In matrix form we have,

$$\begin{bmatrix} \hat{y_1} \\ \hat{y_2} \\ \vdots \\ \hat{y_N} \end{bmatrix} = \begin{bmatrix} 1 & x_1 \\ 1 & x_2 \\ \vdots & \vdots \\ 1 & x_N \end{bmatrix} \begin{bmatrix} w_0 \\ w_1 \end{bmatrix}$$

We can write it as $\hat{Y} = X \times W$. We call X the design matrix.

Least Square Solution: Using Pseudo-Inverse

We can put the desired labels in matrix form as well:

$$Y = \begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_N \end{bmatrix}$$

• Our goal is to minimize the error between Y and \hat{Y} which can be written as $||Y-\hat{Y}||^2$

Exercise: Verify

$$||Y - \hat{Y}||^2 = ||Y - XW||^2 = \sum_{i=1}^{N} ||y_i - (w_0 + w_1 x_i)||^2$$

Multivariable Linear Regression

What if we have multivariable data with x being a vector?

Example:

$$x_i = \begin{bmatrix} x_{i1} \\ x_{i2} \end{bmatrix}$$

$$\hat{y}_1 = w_0 + w_1 x_{11} + w_2 x_{12}$$
$$\hat{y}_2 = w_0 + w_1 x_{21} + w_2 x_{22}$$
$$\vdots$$
$$\hat{y}_N = w_0 + w_1 x_{N1} + w_2 x_{N2}$$

The model can be written in matrix-vector form as:

$$\begin{bmatrix} \hat{y}_1 \\ \hat{y}_2 \\ \vdots \\ \hat{y}_N \end{bmatrix} = \begin{bmatrix} 1 & x_{11} & x_{12} \\ 1 & x_{21} & x_{22} \\ \vdots & \vdots & \vdots \\ 1 & x_{N1} & x_{N2} \end{bmatrix} \begin{bmatrix} w_0 \\ w_1 \\ w_2 \end{bmatrix}$$

Solution remains the same $W = (X^T X)^{-1} X^T Y$
